

Case Study

Energy Resiliency Planning for Building Portfolios

AESC's Solution for One California State Agency

Market Sector

Government Agency

Objective

One CA state agency needed to assess a subset of their building portfolio to determine which buildings could cost effectively become energy resilient and estimate costs to include in their annual budget. The resulting plan would help prioritize and inform future energy efficiency and solar with storage projects that enable critical locations to stay powered on during utility outages.

Approach

This agency utilized AESC's Building Energy Resiliency Planning Services to obtain an expedited resiliency evaluation, including remote energy use analysis for 70+ buildings, 45 of which received a follow up efficiency analysis along with a solar and storage financial analysis.

By the Numbers

70+ Buildings

assessed in as few as 3 weeks

6,400+ kW

Solar generation potential

3,200+ kWh

Battery storage potential

Nearly \$500k

in estimated annual cost savings

Losing power is a losing proposition for state agencies, many of whom have critical infrastructure and buildings that can't afford to shut down.

Increasing occurrences of extreme weather events, along with California utilities proactively shutting off power, means power outages are much more common now than ever before. State agencies with critical building infrastructure need to find solutions to avoid such disruptions. However, with hundreds of buildings in their portfolios, many don't know where to start.

AESC's expedited, remote resiliency evaluation informed this Agency on how to proceed.

Using utility electric interval and billing data, AESC evaluated the potential for each building to pursue energy efficiency, install renewables and pair that with battery energy storage, to reach their target resiliency timeframe.

The Resiliency Ranking Table ranks each building on its resiliency potential, based on its combination of EE, renewable and storage potential. Those in green are the best options, and those in blue are the next best.

| Building | Sq. Ft. | EE Savings (kWh) | EE Savings (%) | Solar System (kW) | Battery Capacity (kWh) | Solar + Battery Payback (Purchase) | Solar + Battery Savings (PPA) | kWh Savings per sq. ft. |
|----------|---------|------------------|----------------|-------------------|------------------------|------------------------------------|-------------------------------|-------------------------|
| A | 72,474 | 191,000 | 23% | 500 | 20 | 13 | \$30,604 | 2.6 |
| K | 20,346 | 45,000 | 18% | 180 | 20 | 13 | \$11,278 | 2.2 |
| C | 73,454 | 36,000 | 4% | 230 | 336 | 17 | \$5,741 | 0.5 |
| O | 26,027 | 75,000 | 23% | 228 | 20 | 13 | \$14,732 | 2.9 |
| EE | 82,680 | 71,000 | 8% | 350 | 20 | 14 | \$17,137 | 0.9 |
| G | 11,708 | 37,000 | 20% | 100 | 34 | 16 | \$3,063 | 3.2 |
| DD | 48,883 | 116,000 | 16% | 240 | 65 | 14 | \$14,006 | 2.4 |
| Q | 124,100 | 112,000 | 14% | 500 | 20 | 14 | \$21,257 | 0.9 |
| B | 73,336 | 59,000 | 7% | 580 | 53 | 11 | \$51,015 | 0.8 |
| D | 73,882 | 36,000 | 4% | 530 | 20 | 13 | \$29,809 | 0.5 |
| S | 20,000 | 59,000 | 15% | 220 | 144 | 12 | \$19,730 | 3.0 |
| P | 16,719 | 45,000 | 23% | 50 | 22 | 13 | \$4,284 | 2.7 |
| KK | 73,870 | 63,000 | 6% | 275 | 42 | 13 | \$15,773 | 0.9 |
| FF | 65,755 | 56,000 | 9% | 280 | 356 | 13 | \$20,221 | 0.9 |
| U | 7,834 | 10,000 | 13% | 51 | 20 | 13 | \$5,178 | 1.3 |
| NN | 18,650 | 27,000 | 3% | 260 | 81 | 11 | \$28,551 | 1.4 |
| E | 11,639 | 21,000 | 16% | 93 | 20 | 11 | \$12,571 | 1.8 |
| T | 24,463 | 36,000 | 18% | 150 | 40 | 15 | \$8,395 | 1.5 |
| J | 36,550 | 31,000 | 8% | 260 | 20 | 11 | \$25,378 | 0.8 |
| M | 20,606 | 17,000 | 18% | 60 | 20 | 12 | \$7,352 | 0.8 |

Low-cost, quick remote assessments to jump-start energy resiliency efforts.

The Process

The work started with reviewing energy usage data for each building. Some buildings were disqualified from further analysis due to factors such as extremely low energy use or insufficient utility data. The remaining buildings were run through AESC’s energy modeling platform, Praxis.

Praxis identified the energy efficiency potential in each building, along with the amount of solar and storage necessary for self-sufficiency. Initially the report was run with a target timeframe of two days. With feedback from the Agency, AESC quickly revised the report to reflect six hours of self-sufficiency.

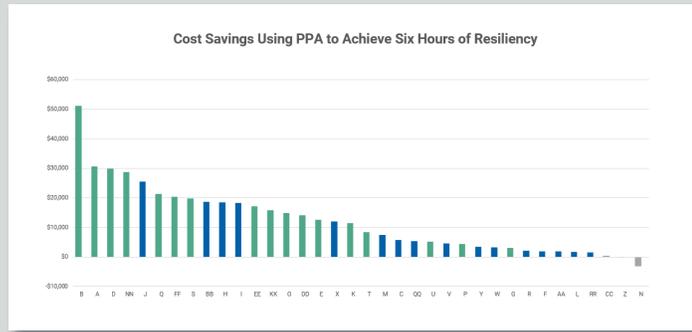

The Results

While all buildings had energy efficiency (EE) potential, in both scenarios there were several buildings that had no potential to cost-effectively reach the target resiliency timeframe. For example, there were small buildings in wooded areas with no discernable place to host a photovoltaic (PV) array, and large buildings whose solar + battery needs were too large to be practical.

As expected, when moving from two days to six hours, the number of buildings that could cost-effectively become resilient increased. For example, looking at one metric – the ability to generate revenue using a power purchase agreement (PPA) – in

The EE Potential Graph shows which buildings have the best EE potential. The highest-ranking resiliency opportunities are in green and blue. It is worth noting that even if there is no resiliency potential, many buildings have excellent EE opportunities.

The Cost Savings Graphs demonstrates the buildings with the best financial cases for the resiliency when a solar PPA is deployed.

the two-day period, approximately one-third of the buildings ranked positively, and in the six-hour time period that percentage jumped to 77%.

Each building received an individual report outlining the various opportunities to save energy, and the financial analysis around the solar and storage pairing. However, with so many buildings, the individual reports were overwhelming. Thus, to simplify decision making, a portfolio-level report was created that ranked the buildings on several factors (see images).

Prioritizing Buildings for Resiliency

Armed with this information, the Agency now knows which buildings to start with when investigating resiliency. This will begin with on-site investigations to dive deeply into the specific EE measures and the exact location and confirmation of sizing for the solar and battery. This resulting report should include line drawings, a power flow analysis, and specifics for equipment that needs to be purchased.

A high-quality report will provide sufficient information to be used in the procurement process – such as an RFP.

As a low-cost, quick to produce report, the remote assessments proved an excellent way to jump-start the Agency's efforts. The data provided a high-level view of all buildings, helping the Agency understand the potential at each. In general, portfolio-level prioritization reduces the need for site visits that might otherwise cause operational interruptions, as it focuses those efforts only where there is the best potential. Additionally, the system costs data provided valuable input for annual budgets and the creation of an energy plan across the portfolio.

Building Energy Resiliency Planning with AESC

AESC's behind-the-meter resiliency work continues, as we help our customers pair electric and gas EE and demand response with solar, wind, and gas renewable solutions plus energy storage.
